ABSTRACT

The effectiveness of horizontal scrub, circular scrub and Fones methods of toothbrushing by professional denial personal in removing denial plaque was studied in 120 subjects representing children and adolescents. The participants were divided into 2 equal groups (60 in each): according to their age. An interaction between method of brushing and brusher was found: illustrating that no one method was clearly most effective in plaque control. Moreover, the individual variations might be considered as a pivotal factor in such studies.
